# 1 Introduction

The Quantum Computing (QC) Benchmark Suite defined within the framework of this contract comprises a set of benchmark cases selected from several domains where Quantum Computing (QC) is being explored for its exponential computing advantage.

Each proposed **Benchmark Case** has four components: the selection criteria, the kernel definition, the test case, and the benchmark execution procedure. And must be complemented by a complete QLM-compatible software implementation and a complete result report into a separate JSON file. This document describes the QLM-reference implementation, the execution procedure as well as the benchmark report format of the following **Benchmark Test Cases**: Probability Loading, PL, Amplitude Estimation, AE, and Quantum Phase Estimation, QPE.

The QLM-reference implementation of the Probability Loading and Amplitude Estimation **Benchmark Test Cases** are based on the Quantum Quantitative Finance Library (QQuantLib), which allows for the implementation of QLM-compatible Probability Loading algorithms and several Amplitude Estimation algorithms used in quantum finances ([3], [6], [9]) as well as the computation of integrals and the expectation value of functions, while that of the Quantum Phase Estimation **Benchmark Test Case** is based on the **rz\_library** which allows for the computation of the eigenvalue of a  $n$  qubits Z-axis rotation unitary operator.

Attached to this documentation is a file - *sourceCodeCases.zip*, which contains all necessary scripts and templates for the **Implementation of the Benchmark Cases of the Suite**. Subsequently, sections [2](#), [3](#), and [4](#), discuss the implementation, execution and report generation of the PL, AE, and QPE **Benchmark Test Cases**.

## 2 Benchmark Test Case Implementation for Probability Loading (PL) Algorithms

The reference implementation for the **Benchmark Test Case** of the **Probability Loading kernel** can be found in the **sourceCodeCases/01-Probability-Loading** folder of the attached file.

This folder contains the following folder and files for implementing and executing the **PL kernel Benchmark Test Case** as well as for generating the benchmark report:

- **QQuantLib** folder: with a complete **QQuantLib** library.
- **load\_probabilities.py**
- **my\_benchmark\_execution.py**
- **my\_environment\_info.py**
- **my\_benchmark\_info.py**
- **my\_benchmark\_summary.py**
- **benchmark.py**

The folder, **QQuantLib**, and the file, **load\_probabilities.py** handle the **PL Benchmark Test Case** implementation, and the file, **my\_benchmark\_execution.py** addresses the **PL Benchmark Test Case** execution. While the files,

**my\_environment\_info.py**, **my\_benchmark\_info.py**, **my\_benchmark\_summary.py** and **benchmark.py** are involved with the benchmark report generation.

In the following sections [2.1](#), [2.2](#) and [2.3](#), we give a detailed description of the actions of the files involved with the implementation and execution of the **Benchmark Test Case** as well as the generation of the benchmark report respectively.

### 2.1 Implementation of the PL Benchmark Test Case

The problem for the **Benchmark Test Case** of the **PL kernel** is the loading of a fixed normal distribution, PDF,  $N_{\mu,\sigma}(x)$  into a quantum circuit. Subsequently, subsection [2.1.1](#) explains how to use the *probability loading* algorithms from **QQuantLib** library while subsection [2.1.2](#) explains the **load\_probabilities.py** script where the Benchmark Test Case workflow can be configured and executed.

#### 2.1.1 The QQuantLib Library for Probability Loading

The *load\_probability* function from the **DL.data\_loading** package of the **QQuantLib** allows to create, from a normalised input numpy array, a **QLM AbstractGate** for encoding it into a quantum circuit. The implementation is based on the algorithm from [\[5\]](#).

Two inputs should be provided to the load probability function:

- *probability\_array*: a numpy array with the desired probability.
- *method*: a string for indicating the loading method to use:
  - *brute-force*: in this case the controlled rotation by state needed by the original algorithm ([\[5\]](#)) were implemented in an straightforward way. This implementation results in a long circuit having a lot of redundant operations.

## 2.1 Implementation of the PL Benchmark Test Case

- *multiplexors*: the mandatory controlled rotation by state were implemented using quantum multiplexors ([10]). This implementation is more efficient and compact.

Listing 1 shows an example for loading an input normalised array into a quantum circuit using the load probability function. In the example, the aforementioned loading methods are used. The circuit implementations for a loading probability operator, using these methods, are presented in figures 1 and 2, for the *brute force* and *multiplexors* methods respectively. As can be seen last method creates more compact circuits.

```

1 from QQuantLib.DL.data_loading import load_probability
2 f_normalised = np.array(
3 [0., 0.14285714, 0.28571429, 0.42857143, 0.57142857, 0.71428571,
4 0.85714286, 1.])
5 #Method: brute_force
6 routine = load_probability(probability, method="brute_force")
7 %qatdisplay routine --depth --svg
8 #Method: multiplexors
9 routine = load_probability(probability, method="multiplexor")
10 #Display circuit representation for multiplexors
11 %qatdisplay routine --depth --svg

```

Listing 1: Loading a probability distribution using the **load\_probability** function from **QQuantLib**. Both loading methods-*brute\_force* and *multiplexors*, were used for the operator creation.

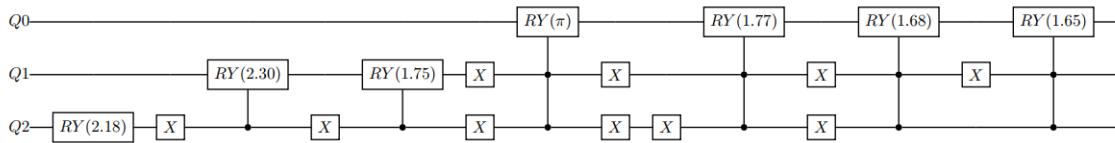

Figure 1: Circuit implementation for brute\_force method of the load\_probability function. Line 7 of listing 1

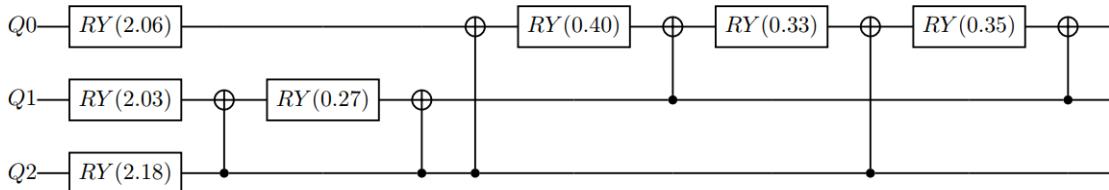

Figure 2: Circuit implementation for for multiplexor method of the load probability function. Line 11 of listing 1

### 2.1.2 load\_probabilities.py

In this script the **Benchmark Test Case** of the **PL kernel**, is implemented as a python class called *LoadProbabilityDensity*. Listing 2 shows the complete class implementation.

## 2.1 Implementation of the PL Benchmark Test Case

```

1  class LoadProbabilityDensity:
2      """
3          Probability Loading

```

Listing 2: *LoadProbabilityDensity* class from **load\_probabilities.py** script.

For instantiating this *LoadProbabilityDensity* a typical python *kwargs* arguments should be provided. The following two keyword arguments are mandatory:

- **n-qubits**: integer with the number of qubits used for loading probability distribution.
- **method**: a string for selecting different **Probability Loading** algorithms. Valid inputs are:
  - *brute-force*: for using load probability function from the **DL.data\_loading** with **direct** implementation see sub section [2.1.1](#).

## 2.2 Execution of the Complete PL Benchmark Procedure

- *multiplexor*: for using load\_probability function from the **DL.data\_loading** with **multiplexors** implementation, see sub section 2.1.1.
- *KPTree*: QLM implementation of a probability loading <sup>1</sup>

The *exe* method executes a complete **Benchmark Test Case** and fills different attributes of the class. Most important is the *pdf* attribute that is a pandas DataFrame where all the configuration and the correspondent metrics results are stored. In the table in figure 3, an example of this attribute is shown. The mean and the sigma columns are the mean and the standard deviation of normal distribution used while the step column corresponds to  $\Delta x$ , which represents the array of values used.

|   | n_qbits | load_method | gpu     | mean     | sigma    | step     | shots | KS       | KL       | chi2      | p_value  | elapsed_time | quantum_time |
|---|---------|-------------|---------|----------|----------|----------|-------|----------|----------|-----------|----------|--------------|--------------|
| 0 | 4       | KPTree      | CLinalg | 0.751392 | 1.247861 | 0.428570 | 20020 | 0.006791 | 0.000692 | 28.046995 | 0.021277 | 0.215811     | 0.210783     |

Figure 3: Example of the pdf attribute from the *LoadProbabilityDensity*

The **load\_probabilities.py** script can be executed from the command line. Different arguments can be provided in order to properly configure the **PL** algorithm and the **Benchmark Test Case**.

Listing 3 shows an example of how to use **load\_probabilities.py** from the command line. In this case, the number of qubits for loading the **PDF** (Probability Density Function) will be 6 and the *multiplexors* method will be used for building the correspondent operator.

```
1 python load_probabilities.py -n_qbits 6 -method multiplexor
```

Listing 3: Example of use the **load\_probabilities.py** script from command line

## 2.2 Execution of the Complete PL Benchmark Procedure

This section explains how to execute a complete benchmark procedure, using the script **my\_benchmark\_execution.py**.

The **my\_benchmark\_execution.py** script is a modification of the corresponding template script, *my\_benchmark\_execution.py*, located in sourceCodeCases/templates folder of the attached file. The functions, **run\_code**, **compute\_samples** and **summarize\_results** were modified; however, the

**KERNEL\_BENCHMARK** class was not modified. The software adaptions for the **PL kernel** is presented in the subsequent subsections.

### run\_code

Listing 4 shows the modifications of the **run\_code** function for the **Benchmark Test Case of the PL kernel**. Its main functionality is executing the **Benchmark Test Case** for a fixed number of qubits (*n\_qbits*), an input number of times (*repetitions*), and gathering all the mandatory metrics obtained. As can be seen, the *LoadProbabilityDensity* class, listing 2, and its *exe* method is used for doing the different executions of the **Benchmark Test Case**.

```
1 1 def run_code(n_qbits, repetitions, **kwargs):
  2      """
  3          For configuration and execution of the benchmark kernel.
```

56     samples_.name = "samples"
57
58     #If user wants limit the number of samples
59     samples_.clip(upper=max_meas, lower=min_meas, inplace=True)
60     return list(samples_)

```

Listing 5: `compute_samples` function for codifying the strategy for computing the number of repetitions for the **Benchmark Test Case** of the **PL kernel**.

### summarize\_results

Listing 6 shows the implementation of the `summarize_results` function for the **Benchmark Test Case** of the **PL kernel**. The main objective of the function is post-processing the results of the complete **Benchmark Test Case** execution.

This function expects that the results of the complete benchmark execution have been stored in a csv file. The function loads this file into a pandas DataFrame that is post-processed properly.

```

1 def summarize_results(**kwargs):
2     """
3         Create summary with statistics
4     """
5
6     folder = kwargs.get("saving_folder")
7     csv_results = folder + kwargs.get("csv_results")
8     #Code for summarize the benchmark results. Depending of the
9     #kernel of the benchmark
10
11    pdf = pd.read_csv(csv_results, index_col=0, sep=";")
12    pdf["classic_time"] = pdf["elapsed_time"] - pdf["quantum_time"]
13    pdf = pdf[
14        ["n_qbits", "load_method", "KS", "KL", "chi2",
15         "p_value", "elapsed_time", "quantum_time", "classic_time"]
16    ]
17    results = pdf.groupby(["load_method", "n_qbits"]).agg(
18        ["mean", "std", "count"])
19
20    return results

```

Listing 6: `summarize_results` function for summarizing the results from the **Benchmark Test Case** execution of the **PL kernel**.

## 2.2 Execution of the Complete PL Benchmark Procedure

### KERNEL\_BENCHMARK class

This python class defines the complete benchmark workflow and its `exe` method executes it properly by calling the correspondent functions (`run_code`, `compute_samples`, `summarize_results`). Each time the **Benchmark Test Case** is executed, the result is stored in a given CSV file.

The only mandatory modification is properly configuring the input keyword arguments at the end of the `my_benchmark_execution.py` script. These parameters will configure the **PL** algorithm, that is, the complete benchmark workflow, and additional options (like the name of the CSV files).

Listing 7 shows an example for configuring an execution of a Benchmark Test Case: in this case the `multiplexor` method will be used for creating the loading operator.

```

1 if __name__ == "__main__":
2
3     kernel_configuration = {
4         "load_method" : "multiplexor",
5         "qpu" : "c", #python, qlmass, default
6     }
7     name = "PL_{}".format(kernel_configuration["load_method"])
8
9     benchmark_arguments = {
10        #Pre benchmark configuration
11        "pre_benchmark": True,
12        "pre_samples": [10],
13        "pre_save": True,
14        #Saving configuration
15        "saving_folder": "./Results/",
16        "benchmark_times": "{}_times_benchmark.csv".format(name),
17        "csv_results": "{}_benchmark.csv".format(name),
18        "summary_results": "{}_SummaryResults.csv".format(name),
19        #Computing Repetitions configuration
20        "relative_error": None,
21        "alpha": None,
22        "min_meas": None,
23        "max_meas": None,
24        #List number of qubits tested
25        "list_of_qbits": [4, 6, 8],
26    }
27
28    #Configuration for the benchmark kernel
29    benchmark_arguments.update({"kernel_configuration":
30        kernel_configuration})
31    ae_bench = KERNEL_BENCHMARK(**benchmark_arguments)
32    ae_bench.exe()

```

Listing 7: Example of configuration of a complete **Benchmark Test Case** execution. This part of the code should be located at the end of the `my_benchmark_execution.py` script.

Possible `kwargs` for the **KERNEL\_BENCHMARK** class, `benchmark_arguments` dictionary in listing 7 are:

- `pre_benchmark`: For executing or not executing the *pre-benchmark* step.

### 2.3 Generation of the PL Benchmark Report

- *pre\_samples*: number of repetitions of the benchmark step.
- *pre\_save*: For saving or not the results from the *pre-benchmark* step.
- *saving\_folder*: Path for storing all the files generated by the execution of the **KERNEL\_BENC\_HMARK** class.
- *benchmark\_times*: name for the *csv* file where the initial and the final times for the complete benchmark execution will be stored.
- *csv\_results*: name for the *csv* file where the obtained metrics for the different repetitions of the benchmark step will be stored.
- *summary\_results*: name for the *csv* file where the post-processed results (using the **summarize\_results** function) will be stored.
- *list\_of\_qbits*: list with the different number of qubits for executing the complete **Benchmark Test Case**.

Other parameters like: *relative\_error*, *alpha*, *min\_meas* or *max\_meas* that are used for the **compute\_samples** can be provided too, but for a complete **Benchmark Test Case** execution must be fixed to *None*. As can be seen in listing 7, the configuration of the implementation of **PL** algorithm is passed in the *benchmark\_arguments* arguments under the key *kernel\_configuration*.

For executing the **Benchmark Test Case**, the following command should be used:

```
python my_benchmark_execution.py
```

## 2.3 Generation of the PL Benchmark Report

The results of a complete **PL Benchmark Test Case** should be reported in a separate JSON file **Benchmark.V2.Schema\_modified.json** provided in the sourceCodeCases/templates folder. For automating this process the following files should be modified:

- **my\_environment\_info.py**
- **my\_benchmark\_info.py**
- **my\_benchmark\_summary.py**
- **benchmark.py**

### 2.3.1 my\_environment\_info.py

This script has the functions for gathering information about the hardware where the **Benchmark Test Case** is executed.

Listing 8 shows an example of the **my\_environment\_info.py** script. Here the compiled information corresponds to a classic computer because the case was simulated instead of executed in a quantum computer.

```

1 import platform
2 import psutil
3 from collections import OrderedDict
4
5 def my_organisation(**kwargs):
    """
```

### 2.3 Generation of the PL Benchmark Report

154

```
    return benchmark
```

Listing 9: Example of configuration of the `my_benchmark_info.py` script

The `my_benchmark_info` function gathers all the mandatory information needed by the `Benchmarks` main field of the report (by calling the different functions listed in listing 9). In order to properly fill this field, some mandatory information must be provided as the typical `python kwargs`:

- `times_filename`: this is the complete path to the file where the starting and ending time of the benchmark was stored. This file must be a `csv` one and it is generated when the **KERNEL\_BENCHMARK** class is executed. This information is used by the `my_starttime` and `my_endtime` functions.
- `benchmark_file`: complete path where the file with the summary results of the benchmark are stored. This information is used by the `summarize_results` function from `my_benchmark_summary.py` script (see section 2.3.3) and for the `my_metadata_info` function for filling the `MetaData` sub-field of `Benchmarks` main field of the report. This `MetaData` sub-field reports the method used for creating the **PL** operator. This field is not mandatory, following the JSON schema used, but it is important to get good traceability of the benchmark results.

#### 2.3.3 my\_benchmark\_summary.py

In this script, the `summarize_results` function is implemented. This function formats the results of a complete execution of a **Benchmark Test Case** of the **PL kernel** with the provided benchmark report format. It can be used for generating the information under the sub-field `Results` of the main field `Benchmarks` in the report.

Listing 10 shows an example of implementation of `summarize_results` function for the **PL** benchmark procedure.

```
1 from collections import OrderedDict
2 import psutil
3
4 def summarize_results(**kwargs):
5     """
6         Mandatory code for properly present the benchmark results following
7         the jsonschema
8     """
9
10    #n_qbits = [4]
11    #Info with the benchmark results like a csv or a DataFrame
12    #pdf = None
13    #Metrics needed for reporting. Depend on the benchmark kernel
14    #list_of_metrics = ["MRSE"]
15
16    import pandas as pd
17    benchmark_file = kwargs.get("benchmark_file", None)
18    pdf = pd.read_csv(benchmark_file, header=[0, 1], index_col=[0, 1])
19    pdf.reset_index(inplace=True)
20    n_qbits = list(set(pdf["n_qbits"]))
21    load_methods = list(set(pdf["load_method"]))
```

### 2.3 Generation of the PL Benchmark Report

```

22     list_of_metrics = [
23         "KS", "KL",
24         "chi2", "p_value"
25     ]
26
27     results = []
28     #In the Probability Loading benchmark several qubits can be tested
29     for n_ in n_qbits:

66     #metric["STD"] = 0.001
67     metric["Value"] = step_pdf[metric_name]["mean"].iloc[0]
68     metric["STD"] = step_pdf[metric_name]["std"].iloc[0]
69     #Depending on the benchmark kernel
70     metric["COUNT"] = int(step_pdf[metric_name]["count"]).
71     iloc[0])
72     metrics.append(metric)
73     result["Metrics"] = metrics
74     results.append(result)
    return results

```

Listing 10: Example of configuration of the *summarize\_results* function for **PL** benchmark

As usual, the *kargs* strategy is used for passing the arguments that the function can use. In this case, the only mandatory argument is *benchmark\_file* with the path to the file where the summary results of the **Benchmark Test Case** execution were stored.

#### 2.3.4 benchmark.py

The *benchmark.py* script can be used directly for gathering all the **Benchmark Test Case** execution information and results, for creating the final mandatory benchmark report.

It is not necessary to change anything about the class implementation. It is enough to update the information of the *kargs* arguments for providing the mandatory files for gathering all the information.

In this case, the following information should be provided as arguments for the *exe* method of the **BENCHMARK** class:

- *times\_filename*: complete path where the file with the times of the **Benchmark Test Case** execution was stored.
- *benchmark\_file*: complete path where the file with the summary results of the **Benchmark Test Case** execution was stored.

### 3 Benchmark Test Case Implementation for Amplitude Estimation (AE) Algorithm

The reference implementation for the **Benchmark Test Case** of the **Amplitude Estimation kernel** can be found in the **sourceCodeCases/02-Amplitude-Estimation** folder of the attached file.

This folder contains the following folder and files for implementing and executing the **AE kernel Benchmark Test Case** as well as for generating the benchmark report:

- **QQuantLib** folder: with a complete copy of the QQuantLib library.
- **jsons** folder: contains several JSON files for configuring the different **AE** algorithms implemented in this library:
  - integral\_mcae\_configuration.json: for a pure **MonteCarlo** solution.
  - integral\_mlae\_configuration.json: for a **MLAE** algorithm.
  - integral\_iqae\_configuration.json: for a **IQAE** algorithm.
  - integral\_rqae\_configuration.json: for a **RQAE** algorithm
  - integral\_cqpeae\_configuration.json: for a **CQPEAE** algorithm.
  - integral\_iqpeae\_configuration.json: for the **IQPAE** algorithm.
- **ae\_sine\_integral.py**
- **my\_benchmark\_execution.py**
- **my\_environment\_info.py**
- **my\_benchmark\_info.py**
- **my\_benchmark\_summary.py**
- **benchmark.py**

The folders, **QQuantLib** and **jsons** and the file, **ae\_sine\_integral.py** handles the **AE Benchmark Test Case** implementation. On the other hand, the file **my\_benchmark\_execution.py** addresses the **AE Benchmark Test Case** execution, while the files, **my\_environment\_info.py**, **my\_benchmark\_info.py**, **my\_benchmark\_summary.py** and **benchmark.py** are involved with the benchmark report generation.

Furthermore, in the directory, **sourceCodeCases/02-Amplitude-Estimation**, of the attached file is a notebook- **\_integral\_computation\_ae.ipynb**, that demonstrates the implementation of the **AE Benchmark Test Case**.

In the following sections [3.1](#), [3.2](#) and [3.3](#), we give a detailed description of the actions of the files involved with the implementation and execution of the Benchmark Test Case as well as the generation of the benchmark report respectively.

#### 3.1 Implementation of the AE Benchmark Test Case

The mathematical problem for the **Benchmark Test Case** of the **AE kernel** is the computation of an integral in a very well-defined interval by using an AE algorithm whose input is an operator **A**, given as:

### 3.1 Implementation of the AE Benchmark Test Case

$$\mathbf{A} |0\rangle_n = \sqrt{a} |\Psi_0\rangle + \sqrt{1-a} |\Psi_1\rangle \quad (1)$$

Where the desired integral is encoded as a Riemann sum into the amplitude of the state  $|\Psi_0\rangle$ , a.

This section presents a complete description of the implementation of **AE kernel Benchmark Test Case**. Subsection 3.1.1 explains how to use the **QQuantLib** library, for computing the different mandatory operators and integrals discussed in the Benchmark test case description; subsection 3.1.2 explains how the **ae\_sine\_integral.py** script is used for implementing the **Benchmark Test Case**.

#### 3.1.1 The QQuantLib Library for Computing Integrals

This subsection explains the software implementation of the different parts of the **Benchmark Test Case**, using the **QQuantLib** library.

##### 3.1.1.1 Operator A Software Implementation

Given a properly normalised input array  $f\_norm_{x_i}$ , the first step is the construction of the operator,  $\mathbf{A}$ :

$$\mathbf{A}(f_{x_i}) = (\mathbb{I} \otimes H^{\otimes n}) \mathbf{U}_f (\mathbb{I} \otimes H^{\otimes n}) \quad (2)$$

Where: the operator  $\mathbf{U}_f$  can be constructed as:

$$\mathbf{U}_f(|0\rangle \otimes |i\rangle_n) = (\mathbf{R}_y(2 * \phi_{x_i}) |0\rangle) \otimes |i\rangle_n \quad (3)$$

Where  $\phi_{x_i} = \arccos(f\_norm_{x_i})$ .

The  $\mathbf{A}(f_{x_i})$  operator can be implemented using the Python class `Encoding` from `QQuantLib.DL.encoding_protocols` belonging to the **QQuantLib** library. This class implements up to 3 different encoding procedures (labeled as 0, 1, and 2) for loading a probability distribution and function as Numpy arrays into a quantum circuit. More information about this class can be found in the notebook- **09-DataEncodingClass.ipynb** located in the folder- **sourceCodeCases/misc/notebooks** of the attached file.

In order to encode the function in a quantum circuit, the following arguments must be passed when the `Encoding` class is instantiated:

- `array_function`: NumPy array with the desired function to encode (this is  $f\_norm_{x_i}$ ).
- `array_probability`: NumPy array with the desired probability function to encode. In the benchmark case, this is the uniform distribution probability - the default distribution of the class, so a `None` must be provided
- `encoding`: for the benchmark case a `2` must be provided.

Once the class is instantiated correctly, the execution of its `run` method creates the QLM implementation (a **QLM QRoutine**) of the operator  $\mathbf{A}(f_{x_i})$ , that is stored in the `oracle` property of the class. Listing 11 shows the use of the `Encoding` class. Figure 4 shows the circuit implementation of the `class_encoding.oracle` (the figure is the output of line 10 of the listing 11).

```

1 from QQuantLib.DL.encoding_protocols import Encoding
2 norm_f_x = np.array([0.17106865, 0.49847362, 0.78295039, 0.99999999])
3 class_encoding = Encoding()

```

### 3.1 Implementation of the AE Benchmark Test Case

```

4     array_function=norm_f_x ,
5     array_probability = None ,
6     encoding=2)
7 class_encoding.run()
8 #QLM circuit oracle implementation
9 oracle_circuit = class_encoding.oracle
10 %qatdisplay oracle_circuit --depth 1

```

Listing 11: Creation of the  $\mathbf{A}^I(f_{x_i})$  operator, using the *Encoding* class from **QQuantLib**, given an input Numpy array *norm\_f\_x*

Following the guidelines of the **AE** algorithm (see subsection 3.2.5 of the Benchmark for Amplitude Estimation Algorithms documentation), the created  $\mathbf{A}(f_{x_i})$  operator should provided as an input of the **AE** algorithm for computing an estimation of the amplitude of the state,  $|\Psi_0\rangle$ ,  $\tilde{a}$ , as shown in:

$$P[|\Psi_0\rangle] = |\langle\Psi_0|\Psi\rangle|^2 = \left| \langle\Psi_0| \frac{1}{2^n} \sum_{i=0}^{2^n-1} f_{norm_{x_i}} |\Psi_0\rangle \right| = \left| \frac{1}{2^n} \sum_{i=0}^{2^n-1} f_{norm_{x_i}} \right|^2 = \tilde{a} \quad (4)$$

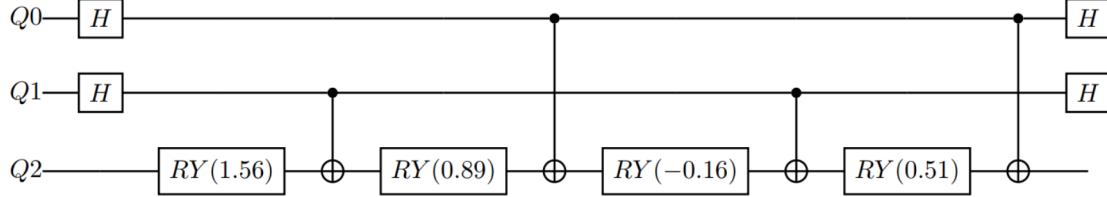

Figure 4: Circuit implementation for the *class\_encoding.oracle* from listing 11

#### 3.1.1.2 Amplitude Estimation Algorithm in QQuantLib

In general, most AE algorithms are based on a Grover-like operator created from the operator  $\mathbf{A}(f_{x_i})$  using equation 5

$$\mathbf{G}(\mathbf{A}(f_{x_i})) = \mathbf{A}(f_{x_i})(\mathbb{I} - 2|0\rangle\langle 0|)\mathbf{A}(f_{x_i})^\dagger(\mathbb{I} - 2|\Psi_0\rangle\langle\Psi_0|) \quad (5)$$

This operator acts as shown in the equation 6:

$$\mathbf{G}^k(\mathbf{A})\mathbf{A}|0\rangle_n = \sin((2k+1)\theta)|\Psi_0\rangle + \cos((2k+1)\theta)|\Psi_1\rangle \quad (6)$$

The Grover function from the *QQuantLib.AA.amplitude\_amplification* module belonging to the QQuantLib library allows to compute, given an input operator  $\mathbf{A}(f_{x_i})$ , the corresponding Grover-like one in a straightforward way as shown in listing 12, where a Grover-like operator is created from the *Encoding* object created in the listing 11.

```

1 from QQuantLib.AA.amplitude_amplification import grover
2 grover_oracle = grover(
3     oracle=class_encoding2.oracle,

```

### 3.1 Implementation of the AE Benchmark Test Case

```

4     target=class_encoding2.target,
5     index=class_encoding2.index
6 )

```

Listing 12: Creation of the correspondent Grover-like operator from an created operator,  $\mathbf{A}^I(f_{x_i})$  operator.

The notebook **02-Amplitude-Amplification-Operators.ipynb**, in the folder `sourceCodeCases/misc/notebooks`, provides more information about this Grover function.

**Note:** most **AE** algorithms rely on the Grover-like operator, but there are some algorithms where other operators are used. The **Benchmark Test Case for AE kernel** described in this document is agnostic about these operators. The only mandatory input is the **A** operator.

- CQPEAE (*ae\_classical\_qpe module*) uses a classical phase estimation algorithm with QFT, see Figure 5, [1]. See notebook **sourceCodeCases/misc/notebooks/03-Maximum-Likelihood-Amplitude-Estimation-Class** for more information.
- IQPEAE (*ae\_iterative\_quantum\_pe module*) uses an iterative implementation of QFT, using only one additional qubit, for classical phase estimation ([2], [7]). See notebook **sourceCodeCases /misc/notebooks/05-Iterative-Quantum-Phase-Estimation-Class.ipynb** for more information.
- MLAE (*maximum\_likelihood\_ae module*) uses a Maximum Likelihood algorithm [11]. See notebook **sourceCodeCases/misc/notebooks/03-Maximum-Likelihood-Amplitude-Estimation Class.ipynb** for more information.
- IQAE (*iterative\_quantum\_ae module*) uses an algorithm based on iterative applications of the Grover-like operator  $\mathbf{G}(\mathbf{A}(f_{x_i}))$  [4]. See notebook **sourceCodeCases/misc/notebooks/06-Iterative-Quantum-Amplitude-Estimation-class.ipynb** for more information.
- RQAE (*real\_quantum\_ae module*) uses an algorithm based on iterative applications of the Grover-like operator,  $\mathbf{G}(\mathbf{A}(f_{x_i}))$  [8]. See notebook **sourceCodeCases/misc/notebooks/07-Real-Quantum-Amplitude-Estimation-class.ipynb** for more information.
- MCAE (*montecarlo\_ae\_module*) uses the Monte Carlo algorithm. See notebook **sourceCodeCases/misc/notebooks/08-AmplitudeEstimation-Class.ipynb** for more information.

### 3.1 Implementation of the AE Benchmark Test Case

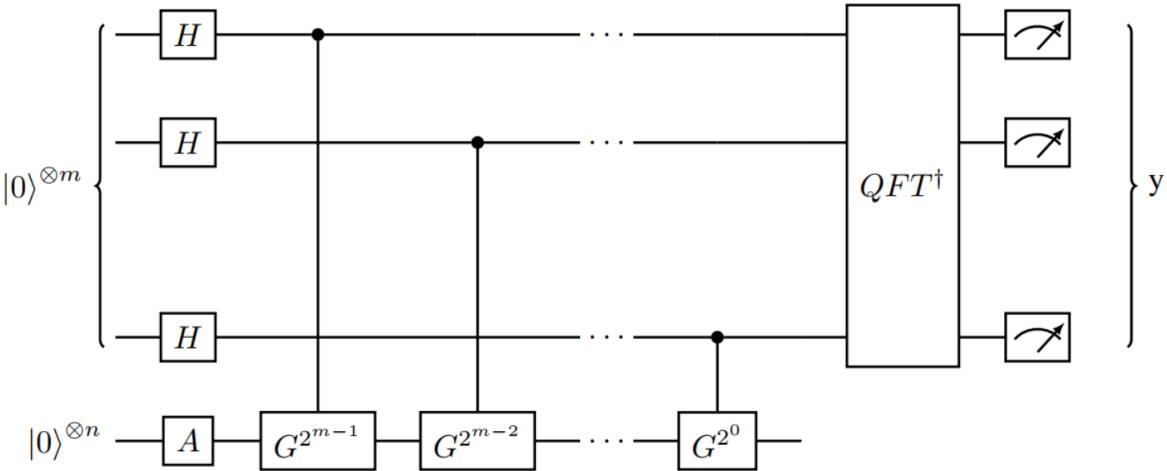

Figure 5: Canonical Amplitude Estimation using Quantum Phase Estimation

All of the algorithms in the bulleted list above use the *Grover* function explained in listing 12 to create the Grover-like operator. **QQuantLib** implements all the **AE** algorithms as Python classes that can be used in a similar way: each class should be instantiated passing the following parameters:

- oracle: A QLM AbstractGate or QRoutine with the implementation of the Oracle (the *oracle* property from a *Encoding* class can be used).
- target: this is the marked state in a binary representation as a Python list (the *target* property from a *Encoding* class can be used).
- index: a list of the qubits affected by the Oracle operator (the *index* property from a *Encoding* class can be used).
- kwargs: a typical Python *keyword* arguments where the different keywords can be used to configure different parameters of the **AE** algorithm. Configuration examples for the different **AE** algorithms can be found in the JSON files inside the **sourceCodeCases/02-Amplitude-Estimation/jsons** folder of the attached file.

The *run* method of the class is then executed and the estimator  $\tilde{a}$  is computed and returned using the properly configured **AE** algorithm (additionally it is stored in the *ae* property of the method).

Additionally, a class called *AE*, implemented in the module *ae\_class* into the *QQuantLib.AE* package, can be used for selecting one of the available **AE** algorithms. In this case, another argument *ae\_type* can be provided for selecting the algorithm- this argument is a Python string that can take the following values: [MLAE, CQPEAE, IQPEAE, IQAE, RQAE, MCAE] to select the appropriate **AE** algorithm. In this class, the desired estimator is stored as a Pandas DataFrame into the *ae\_pdf* property of the class. Listing 13 shows how to use this class. The *Encoding* object from listing 11, is used for providing the mandatory  $\mathbf{A}(f_{x_i})$  operator to the class.

```

```

Listing 13: Example of how to use the general **AE** class from *QQuantLib.AE* package. The Encoding class can be used for providing the mandatory  $\mathbf{A}(f_{x_i})$  operator in a transparent way

The notebook **sourceCodeCases/misc/notebooks/08-Amplitude Estimation-Class.ipynb** provides more information about this class.

#### 3.1.1.3 Amplitude vs Probability Estimation

In general, the **AE** algorithms compute the probability of the state  $|\Psi_0\rangle$ , instead of its amplitude. This is true for all the **AE** algorithms implemented in the **QQuantLib** library except for the **RQAE** one where the amplitude of such state is returned (thus it can be negative). Taking this into account, equation 1 can be rewritten as:

$$|\Psi\rangle = \mathbf{A}|0\rangle \otimes |0\rangle_n = \begin{cases} \sqrt{a}|\Psi_0\rangle + \sqrt{1-a}|\Psi_1\rangle & \text{NO RQAE} \\ a|\Psi_0\rangle + \beta|\Psi_1\rangle & \text{RQAE} \end{cases} \quad (7)$$

### 3.1 Implementation of the AE Benchmark Test Case

Only the  $|\Psi\rangle = |0\rangle \otimes |0\rangle_n$  term must be taken into account, so using equation 7, the equation in 4, is now transformed into:

$$\tilde{a} = \begin{cases} \mathbf{P}_{\Psi_0} = \left| \frac{1}{2^n} \sum_{i=0}^{2^n-1} f\_norm_{x_i} \right|^2 & \text{NO RQAE} \\ \mathbf{Amplitude}_{\Psi_0} = \frac{1}{2^n} \sum_{i=0}^{2^n-1} f\_norm_{x_i} & \text{RQAE} \end{cases} \quad (8)$$

So the desired sum in the **AE** estimation is:

$$\sum_{i=0}^{2^n-1} f\_norm_{x_i} = \begin{cases} 2^n \sqrt{a} & \text{NO RQAE} \\ 2^n a & \text{RQAE} \end{cases} \quad (9)$$

In order to use the **QQuantLib** implemented algorithms for the **Benchmark Test Case** of the **AE kernel** equation 9 must be used for recovering the desired integral instead of equation of equation 4.

The function, **q\_solve\_integral**, from *QQuantLib.finance.quantum\_integration* module allows the computation of the integrals of input arrays by using **AE** techniques in a transparent way. This function, computes the integral using equation 9, taking into account the **AE** algorithm used, and returning directly the integral of the input array function:  $2^n \sqrt{a}$ (or the  $2^n a$  for the **RQAE** algorithm).

The input of this function will be a Python *kwargs* where the different keys allow the complete configuration of the data encoding, the **AE** algorithm configuration, etc. The most important keywords are:

- **array\_function** : NumPy array with the desired array function for Riemann sum.
- **array\_probability** : Numpy array with a probability distribution for the computation of the expected values. In the benchmark case this will be None (so a uniform distribution probability will be used).
- **encoding**: int for selecting the encoding. In the **Benchmark Test Case**, its value will be 2.
- **ae\_type**: string for providing the **AE** algorithm for solving the desired integral.

The outputs of the **q\_solve\_integral** function are:

- **ae\_estimation**: pandas DataFrame with the desired integral computation and the upper and lower limits if applied (depending one the **AE** algorithm).
- **solver\_ae**: object based on the *AE* class.

Listing 14 shows how to use *q\_solve\_integral* for computing the integral of an input numpy array by using 2 different **AE** algorithms in a straightforward way.

```

1 from QQuantLib.finance.quantum_integration import q_solve_integral
2 norm_f_x = np.array([0.17106865, 0.49847362, 0.78295039, 0.99999999])
3

### 3.1 Implementation of the AE Benchmark Test Case

```

52 #Results
53 Desired Riemann integral: 2.45249265
54 IQAE integral computation: 2.4531461375134835
55 RQAE integral computation: 2.4534891011970776

```

Listing 14: Using `q_solve_integral` for solving the integral of an input array using the encoding procedure 2 and two different **AE** algorithms.

Finally, equation 9 must be plugged into the Riemann sum:

$$S_{[a,b]} = \frac{b-a}{2^n} \sum_{i=0}^{2^n-1} f_{x_i} = \frac{b-a}{2^n} \sum_{i=0}^{2^n-1} \max(|f_{x_i}|) f\_norm_{x_i} = \frac{\max(|f_{x_i}|)(b-a)}{2^n} \sum_{i=0}^{2^n-1} f\_norm_{x_i} \quad (10)$$

for obtaining the desired integral as shown in equation 11

$$\tilde{S}_{[a,b]} = \begin{cases} \frac{\max(f_{x_i})(b-a)}{2^n} (2^n \sqrt{a}) & \text{NO RQAE} \\ \frac{\max(f_{x_i})(b-a)}{2^n} (2^n a) & \text{RQAE} \end{cases} \quad (11)$$

#### 3.1.2 ae\_sine\_integral.py

In this script, the **Benchmark Test Case** for the **AE** kernel is implemented in the function `sine_integral`. This function needs as inputs:

- `n_qbits`: number of quits used for integral domain discretization.
- `interval`: for selecting with integration interval, computed as:
  - 0:  $[0, \frac{3\pi}{8}]$
  - 1:  $[\pi, \frac{5\pi}{4}]$
- `ae_dictionary`: python dictionary with the complete **AE** algorithm. configuration.

The function, `sine_integral`, returns a pandas DataFrame with the complete information of the executed **Benchmark Test Case** (this includes the configuration of the **AE** algorithm, the interval used, the qpu used and the obtained results). The complete code is shown in listing 15.

```

1 def sine_integral(n_qbits, interval, ae_dictionary):
2     """
3         Function for solving the sine integral between two input values:
4
5             Parameters

```

Listing 15: *sine\_integral* function from **ae\_sine\_integral.py** script.

In order to configure properly the **AE** algorithm, the JSON files in the **sourceCodeCases/02-Amplitude-Estimation/jsons** can be edited and loaded as a dictionary that can be provided to the *sine\_integral* function.

The **ae\_sine\_integral.py** script can be executed from the command line. Different arguments can be provided in order to properly configure the integral computation.

The usage guide of the **ae\_sine\_integral.py** script is obtained using the *-h* parameter.

Listing 16 shows an example of how to use **ae\_sine\_integral.py** from the command line. In this case, the domain interval will be the 0; 4 qubits will be used for domain discretization, and the Maximum Likelihood Amplitude Estimation (MLAE) algorithm will be used for computing the integral. In this case, the algorithm is configured using the **sourceCodeCases/jsons/integral\_mlae\_configuration.json** file.

```

1 python ae_sine_integral.py -n_qbits 4 -interval 0 -ae_type MLAE -qpu
    python --save --folder Results --exe

```

Listing 16: Example of the usage of the **ae\_sine\_integral.py** script from the command line.

## 3.2 Execution of the Complete AE Benchmark Procedure

This section explains how to execute a complete benchmark procedure, using the script **my\_benchmark\_execution.py**.

The **my\_benchmark\_execution.py** script is a modification of the corresponding template script located in sourceCodeCases/templates folder of the attached file. The functions, **run\_code**, **compu-**

### 3.2 Execution of the Complete AE Benchmark Procedure

`te_samples` and `summarize_results` were modified; however, `KERNEL_BENCHMARK` class was not modified. The software adaptions for the **AE kernel** as presented in the subsequent sections.

#### run\_code

Listing 17 shows the modifications of the `run_code` function for the **Benchmark Test Case** of the **AE kernel**. The main functionality of the function is executing the **Benchmark Test Case** for a fixed number of qubits (`n_qbits`), an input number of times (`repetitions`), and gathering all the mandatory metrics obtained- this step is done by the `sine_integral` function (see listing 15).

```

1 def run_code(n_qbits, repetitions, **kwargs):
2     """
3         For configuration and execution of the benchmark kernel.
4
5     Parameters
6     -----

17
18    metrics : pandas DataFrame
19        DataFrame with the desired metrics obtained for the integral
computation
20
21    """
22    if n_qbits is None:
23        raise ValueError("n_qbits CAN NOT BE None")
24    if repetitions is None:
25        raise ValueError("samples CAN NOT BE None")
26
27    from ae_sine_integral import sine_integral
28    #Here the code for configuring and execute the benchmark kernel
29    ae_configuration = kwargs.get("ae_configuration")
30    print(ae_configuration)
31    ae_configuration.update({"qpu": kwargs['qpu']})
32
33    columns = [
34        "interval", "n_qbits", "absolute_error_sum", "oracle_calls",
35        "elapsed_time", "run_time", "quantum_time"
36    ]
37
38    list_of_metrics = []
39    for j, interval in enumerate([0, 1]):
```

### 3.2 Execution of the Complete AE Benchmark Procedure

```

40     for i in range(repetitions[j]):
41         metrics = sine_integral(n_qbits, interval, ae_configuration
42 )
43             list_of_metrics.append(metrics)
44 metrics = pd.concat(list_of_metrics)
45 metrics.reset_index(drop=True, inplace=True)
46 return metrics[columns]

```

Listing 17: `run_code` function for the **Benchmark Test Case** of the **AE kernel**.

### compute\_samples

Listing 18 shows the implementation of the `compute_samples` function for the **Benchmark Test Case** of the **AE kernel**. The main objective of the function, is to codify a strategy for computing the number of times, the **Benchmark Test Case** should be executed for getting some desired statistical significance.

```

1 def compute_samples(**kwargs):
2 """
3     This functions computes the number of executions of the benchmark
4     for assure an error r with a confidence of alpha
5
6     Parameters
7     -----
8
9     kwargs : keyword arguments
10        For configuring the sampling computation
11
12    Returns
13    -----

23    relative_error = kwargs.get("relative_error", None)
24    if relative_error is None:
25        relative_error = 0.1
26    #Desired Confidence level
27    alpha = kwargs.get("alpha", None)
28    if alpha is None:
29        alpha = 0.05
30    #Minimum and Maximum number of samples
31    min_meas = kwargs.get("min_meas", None)
32    if min_meas is None:

```

### 3.2 Execution of the Complete AE Benchmark Procedure

```

33     min_meas = 5
34     max_meas = kwargs.get("max_meas", None)
35     #if max_meas is None:
36     #    max_meas = 100
37
38     #Code for computing the number of samples for getting the desired
39     #statistical significance. Depends on benchmark kernel
40     #samples_ = pd.Series([100, 100])
41     #samples_.name = "samples"
42
43     #Compute mean and sd by integration interval
44     metrics = kwargs.get("pre_metrics")
45     std_ = metrics.groupby("interval").std()
46     std_.reset_index(inplace=True)
47     mean_ = metrics.groupby("interval").mean()
48     mean_.reset_index(inplace=True)
49
50     columns = [
51         "absolute_error_sum", "oracle_calls",
52         "elapsed_time", "run_time", "quantum_time"
53     ]
54
55     #Metrics
56     from scipy.stats import norm
57     zalpha = norm.ppf(1-(alpha/2)) # 95% of confidence level
58     samples_ = (zalpha * std_[columns] / (relative_error * mean_[
59     columns]))**2
60     samples_ = samples_.max(axis=1).astype(int)
61     samples_.name = "samples"
62
63     #If user wants limit the number of samples
64     samples_.clip(upper=max_meas, lower=min_meas, inplace=True)
       return list(samples_)

```

Listing 18: `compute_samples` function for codifying the strategy for computing the number of repetitions for the **Benchmark Test Case** of the **AE kernel**.

### summarize\_results

Listing 19 shows the implementation of the `summarize_results` function for the **Benchmark Test Case** of the **AE kernel**. The main objective of the function is post-processing the results of the complete **Benchmark Test Case** execution.

This function expects that the results of the complete benchmark execution have been stored in a csv file. The function loads this file into a pandas DataFrame that is post-processed properly.

```

1 def summarize_results(**kwargs):
2     """
3         Create summary with statistics
4     """

```

### 3.2 Execution of the Complete AE Benchmark Procedure

```

5
6     #Code for summarize the benchmark results. Depending of the
7     #kernel of the benchmark
8     folder = kwargs.get("saving_folder")
9     csv_results = folder + kwargs.get("csv_results")
10
11    #results = pd.DataFrame()
12    pdf = pd.read_csv(csv_results, index_col=0, sep=";")
13    pdf["classic_time"] = pdf["elapsed_time"] - pdf["quantum_time"]
14    results = pdf.groupby(["interval", "n_qbits"]).describe()
15
16    return results

```

Listing 19: **summarize\_results** function for summarizing the results from the **Benchmark Test Case** execution of the **AE** kernel.

### KERNEL\_BENCHMARK class

This python class defines the complete benchmark workflow and its *exe* method executes it properly by calling the correspondent functions (**run\_code**, **compute\_samples**, **summarize\_results**). Each time the **Benchmark Test Case** is executed, the result is stored in a given CSV file.

The only mandatory modification is properly configuring the input keyword arguments at the end of the **my\_benchmark\_execution.py** script. These parameters will configure the **AE** algorithm, that is, the complete benchmark workflow, and additional options (like the name of the CSV files).

Listing 20 shows an example for configuring an execution of an **IQAE** algorithm. The **source-Cod eCases/02-Amplitude-Estimation/jsons/integral\_iqae\_configurations.json** file is used for the **AE** algorithm configuration.

```

1 if __name__ == "__main__":
2     from ae_sine_integral import select_ae
3
4     AE = "IQAE"
5     benchmark_arguments = {
6         #Pre benchmark configuration
7         "pre_benchmark": True,
8         "pre_samples": [10, 10],
9         "pre_save": True,
10        #Saving configuration
11        "saving_folder": "./IQAE_Results/",
12        "benchmark_times": "{}_times_benchmark.csv".format(AE),
13        "csv_results": "{}_benchmark.csv".format(AE),
14        "summary_results": "{}_SummaryResults.csv".format(AE),
15        #Computing Repetitions configuration
16        "relative_error": None,
17        "alpha": None,
18        "min_meas": None,
19        "max_meas": None,
20        #List number of qubits tested
21        "list_of_qubits": [4, 6, 8, 10],

```

### 3.2 Execution of the Complete AE Benchmark Procedure

```

22     "qpu": "c"
23 }
24 #Setting the AE algorithm configuration
25 ae_problem = select_ae(AE)
26 #Added QPU to ae_problem
27 #ae_problem.update({"qpu":benchmark_arguments["qpu"]})
28
29 json_object = json.dumps(ae_problem)
30 #Writing the AE algorithm configuration
31 conf_file = benchmark_arguments["saving_folder"] + \
32     "benchmark_ae_conf.json"
33 with open(conf_file, "w") as outfile:
34     outfile.write(json_object)
35 #Added ae configuration
36 benchmark_arguments.update({
37     "ae_configuration": ae_problem,
38 })
39 ae_bench = KERNEL_BENCHMARK(**benchmark_arguments)
40 ae_bench.exe()

```

Listing 20: Example of configuration of a complete **Benchmark Test Case** execution. This part of the code should be located at the end of the `my_benchmark_execution.py` script.

Possible *kargs* for the **KERNEL\_BENCHMARK** class, `benchmark_arguments` dictionary in listing 20 are:

- *pre\_benchmark*: For executing or not executing the *pre-benchmark* step.
- *pre\_samples*: number of repetitions of the benchmark step. The first element is for the integration interval **0** and the second for the interval **1**.
- *pre\_save*: For saving or not the results from the *pre-benchmark* step.
- *saving\_folder*: Path for storing all the files generated by the execution of the **KERNEL\_BENCH MARK** class.
- *benchmark\_times*: name for the *csv* file where the initial and the final times for the complete benchmark execution will be stored.
- *csv\_results*: name for the *csv* file where the obtained metrics for the different repetitions of the benchmark step will be stored.
- *summary\_results*: name for the *csv* file where the post-processed results (using the **summarize\_results** function) will be stored.
- *list\_of\_qbits*: list with the different number of qubits for executing the complete **Benchmark Test Case**.

Other parameters like: *relative\_error*, *alpha*, *min\_meas* or *max\_meas* that are used for the **compute\_samples** function can be provided too, but for a complete **Benchmark Test Case** execution must be fixed to *None*.

As can be seen in the listing 20 the configuration of the implementation of **AE** algorithm is passed in the `benchmark_arguments` arguments under the key *ae\_configuration*. The methods of the class send it as *kargs* to the different functions of the scripts in a transparent way.

### 3.3 Generation of the AE Benchmark Report

Listing 20 is located at the end of the **my\_benchmark\_execution.py** script. The different parts of the **Benchmark Test Case** complete execution and the **AE** algorithm used can be easily changed (the **AE** algorithm configuration can be changed by editing the corresponding JSON). For executing the **Benchmark Test Case**, the following command should be used:

```
python my_benchmark_execution.py
```

Finally, it is worth to comment lines 30-35 of the listing 20: here the configuration of the **AE** algorithm will be saved to JSON format file for traceability purposes.

## 3.3 Generation of the AE Benchmark Report

The results of a complete **AE Benchmark Test Case** must be reported in a separate JSON file- **Benchmark.V2.Schema\_modified.json** provided in the sourceCodeCases/templates folder. For automating this process the following files should be modified:

- **my\_environment\_info.py**
- **my\_benchmark\_info.py**
- **my\_benchmark\_summary.py**
- **benchmark.py**

### 3.3.1 my\_environment\_info.py

This script has the functions for gathering information about the hardware where the **Benchmark Test Case** is executed.

Listing 21 shows an example of the **my\_environment\_info.py** script. Here the compiled information corresponds to a classic computer because the case was simulated instead of executed in a quantum computer.

```

1 import platform
2 import psutil
3 from collections import OrderedDict
4
5 def my_organisation(**kwargs):
6     """
7         Given information about the organisation how uploads the benchmark
8     """
9     name = "CESGA"
10    return name
11
12 def my_machine_name(**kwargs):
13     """
14         Name of the machine where the benchmark was performed
15     """
16     machine_name = platform.node()
17     return machine_name
18
19 def my_qpu_model(**kwargs):
20     """

```

### 3.3 Generation of the AE Benchmark Report

```

21     Name of the model of the QPU
22     """
23
24     qpu_model = "QLM"
25     return qpu_model
26
27
28 def my_qpu(**kwargs):
29     """
30     Complete info about the used QPU

Listing 22: Example of configuration of the `my_benchmark_info.py` script

The `my_benchmark_info` function gathers all the mandatory information needed by the *Benchmarks* main field of the report (by calling the different functions listed in listing 22). In order to properly fill this field, some mandatory information must be provided as the typical *python kwargs*:

- `times_filename`: this is the complete path to the file where the starting and ending time of the benchmark was stored. This file must be a *csv* one and it is generated when the **KERNEL\_BENCHMARK** class is executed. This information is used by the `my_starttime` and `my_endtime` functions.
- `ae_config`: complete path where the configuration of the AE algorithm used in the benchmark (in JSON format) is stored (see last paragraph of subsection 3.2). This information is used by the `my_metadata_info` function for filling the *MetaData* sub-field of Benchmarks main field of

### 3.3 Generation of the AE Benchmark Report

the report. This field is not mandatory, following the JSON schema used, but it is important to get good traceability of the benchmark results.

- *benchmark\_file*: complete path where the file with the summary results of the benchmark are stored. This information is used by the *summarize\_results* function from *my\_benchmark\_summary.py* script (see section 3.3.3).

#### 3.3.3 my\_benchmark\_summary.py

In this script, the *summarize\_results* function is implemented. This function formats the results of a complete execution of a **Benchmark Test Case** of the **AE kernel** with the provided benchmark report format. It can be used for generating the information under the sub-field *Results* of the main field *Benchmarks* in the report.

Listing 23 shows an example of implementation of *summarize\_results* function for the **AE** benchmark procedure.

```

1  from collections import OrderedDict
2  import psutil
3
4  def summarize_results(**kwargs):

### 3.3 Generation of the AE Benchmark Report

73      `return results`

Listing 23: Example of configuration of the `summarize_results` function for **AE** benchmark

As usual, the `kwarg`s strategy is used for passing the arguments that the function can use. In this case, the only mandatory argument is `benchmark_file` with the path to the file where the summary results of the **Benchmark Test Case** execution were stored.

#### 3.3.4 benchmark.py

The `benchmark.py` script can be used directly for gathering all the **Benchmark Test Case** execution information and results, for creating the final mandatory benchmark report.

It is not necessary to change anything about the class implementation. It is enough to update the information of the `kwarg`s arguments for providing the mandatory files for gathering all the information.

In this case, the following information should be provided as arguments for the `exe` method of the **BENCHMARK** class:

- `times_filename`: complete path where the file with the times of the **Benchmark Test Case** execution was stored.
- `benchmark_file`: complete path where the file with the summary results of the **Benchmark Test Case** execution was stored.
- `ae_config`: complete path where the configuration of the **AE** algorithm used in the benchmark (in JSON format) was stored.

## 4 Benchmark Test Case Implementation for Quantum Phase Estimation (QPE) Algorithms

The reference implementation for the **Benchmark Test Case** of the **Quantum Phase Estimation kernel** can be found in the **sourceCodeCases/03-Phase-Estimation** folder of the attached file.

This folder contains the following folder and files for implementing and executing the **QPE kernel Benchmark Test Case** as well as for generating the benchmark report:

- **QPE** folder: with the following files-
  - data\_extracting.py: a module for executing QLM programs based on QLM Operators and for post-processing results from QLM QPU executions.
  - qpe.py: Script for executing classical Phase Estimation.
  - qpe\_rz.py: Python class for executing the  $n$  qubits unitary operator,  $R_z^{\otimes n}(\vec{\theta})$ , for the **Benchmark Test Case**.
  - rz\_lib.py: Script for executing theoretical and QLM simulation for computing the eigenvalues of the **Benchmark Test Case** unitary operator.
  - rz qlm.py: Script for executing the QLM simulation for computing the eigenvalues of the unitary operator of the **Benchmark Test Case**.
- benchmark\_exe.sh
- my\_benchmark\_execution.py
- my\_benchmark\_info.py
- my\_benchmark\_summary.py
- my\_environment\_info.py
- benchmark.py

The folder, **QPE**, handles the **QPE Benchmark Test Case** implementation and the files **my\_benchmark\_execution.py** and **benchmark\_exe.sh.py** addresses the **PE kernel Benchmark Test Case** execution. While the files, **my\_benchmark\_info.py**, **my\_benchmark\_summary.py**, **my\_environment\_info.py** and **benchmark.py** are involved with the benchmark report generation.

Other files in the directory of the QPE of the attached file are python notebooks which demonstrates the **QPE kernel Benchmark Test Case** implementation and execution. They are:

1. 01\_BTC\_03\_QPE\_for\_rzn\_rz\_library.ipynb
2. 02\_BTC\_03\_QPE\_for\_rzn\_Procedure.ipynb
3. 03\_BTC\_03\_QPE\_for\_rzn\_my\_benchmark\_execution.ipynb

In the following sections [4.1](#), [4.2](#) and [4.3](#), we give a detailed description of the actions of the files involved with the implementation and execution of the **Benchmark Test Case** as well as the generation of the benchmark report respectively.

## 4.1 Implementation of the QPE Benchmark Test Case

The problem for the **Benchmark Test Case** of the **QPE kernel** is the computation of the eigenvalues of a  $n$  qubits unitary operator given as:

$$R_z^{\otimes n}(\vec{\theta}) = \otimes_{i=1}^n R_z(\theta_i) \quad (12)$$

for a vector of  $n$  angles  $\vec{\theta} = \{\theta_i\}; i = 0, 1, n - 1$

Where: the  $R_z(\theta)$  operator is a Z-axis rotation gate given by equation (13).

$$R_z(\theta) = (e^{-i\frac{\theta}{2}} |0\rangle\langle 0| + e^{i\frac{\theta}{2}} |1\rangle\langle 1|) \quad (13)$$

The QLM-reference implementation of the **QPE Benchmark Test Case**, makes use of the **rz\_library**, a python package with all necessary functions for computing the eigenvalues of the  $n$  qubits  $R_z^{\otimes n}(\vec{\theta})$  operator.

This section presents a complete description of the implementation of **QPE kernel Benchmark Test Case**. Subsections 4.1.1 and 4.1.2 discusses the library and class used in the implementation of the **QPE Benchmark Test Case**.

### 4.1.1 The rz\_library for Computing Eigenvalues

The **rz\_library** has been developed with all important functions for executing the theoretical and QLM simulation of the **QPE Benchmark Test Case**- the computation of eigenvalues of a  $n$  qubits  $R_z^{\otimes n}(\vec{\theta})$  unitary operator. It is located in sourceCodeCases/03-Phase-Estimation/QPE/rz\_lib.py of the attached file and the **qpe\_class** in subsection 4.1.2 is defined within the framework of the **rz\_library**.

### 4.1.2 qpe\_rz.py: the QPE\_RZ class

The **QPE\_RZ** class located in sourceCodeCases/03-Phase-Estimation/QPE/qpe\_rz.py has been developed for executing the complete benchmark step procedure for the **QPE kernel**. The description of how to use this class is given in the notebook located in sourceCodeCases/03-Phase-Estimation/02\_BTC\_03\_QPE\_for\_rzn\_Procedure.ipynb. The functions implemented *QPE\_RZ* class are already defined with the framework of the **rz\_library** and the mandatory arguments that must be passed when this class is instantiated are:

- **number\_of\_qbits**: the number of qubits for apply the Kronecker products of  $R_z$ .
- **auxiliar\_qbits\_number**: auxiliary number of qubits for executing the **QPE Benchmark Test Case**.
- **angles**: the angles for the  $R_z^{\otimes n}(\vec{\theta})$  operator. It can be:
  - float number: the same angle to all  $R_z$ .
  - list with angles: Each angle will be applied to a  $R_z$ . The Number of elements MUST be equal to the number of qubits.
  - string: Two different strings can be provided:
    - \* random: random angles will be provided to each  $R_z$ .

#### 4.1 Implementation of the QPE Benchmark Test Case

- \* exact: In this case, random angles will be provided to each  $R_z$ , but the final result will have a precision related to the number of auxiliary qubits for the **QPE Test Case**.

Listing 24 demonstrates the initializing of the *QPE\_RZ* class:

```

1 import numpy as np
2 import pandas as pd
3
4 # myQLM qpus
5 from qat.qpus import PyLinalg, CLinalg
6 qpu_c = CLinalg()
7 qpu_p = PyLinalg()
8
9 from QPE.qpe_rz import QPE_RZ
10
11 n_qbits = 5
12 # Fix the precision of the QPE
13 aux_qbits = 6
14 # angles
15 angles = [np.pi / 2.0 for i in range(n_qbits)]
16 # Dictionary for configuring the class
17 qpe_dict = {
18     'number_of_qbits' : n_qbits,
19     'auxiliar_qbits_number' : aux_qbits,
20     'angles' : angles,
21     #'angles' : 'random',
22     'qpu' : qpu_c,
23     'shots' : 0
24 }
```

Listing 24: Initializing the *QPE\_RZ* class.

Now, we discuss the Implementation of the main steps of the Benchmark Test Case with respect to the **rz\_library** and the **QPE\_RZ class** under the following headings:

1. Generation of the reference / theoretical probability distribution of the eigenvalues of  $R_z^{\otimes n}(\vec{\theta})$  using the **rz\_library**
2. Implementation of the Reference / Theoretical Probability Distribution of the eigenvalues of  $R_z^{\otimes n}(\vec{\theta})$  using the **QPE\_RZ class**
3. Computation of the Number of Shots for Simulating the PE Circuit on the Quantum Device
4. Generation of the QPE Probability Distribution of the Eigenvalues of  $R_z^{\otimes n}(\vec{\theta})$  using the **rz\_library**
5. Implementation of the QPE probability distribution of the eigenvalues of  $R_z^{\otimes n}(\vec{\theta})$  using the **QPE\_RZ class**.
6. Computing the metrics
7. Implementing the complete **QPE Benchmark Test Case** (subsection)

The steps 1-7 above are explained as follows-

1. **Generation of the reference / theoretical probability distribution of the eigenvalues of R\_z using the rz\_library**

## 4.1 Implementation of the QPE Benchmark Test Case

In this section, using a bulleted list, we discuss the steps and functions for generating a reference probability distribution,  $P_{\lambda,m}^{\text{th}}(\frac{k}{2^m})$ ;  $k = 1, 2, \dots, 2^m$  of the eigenvalues using the **rz\_library** located in **sourceCodeCases/03-Phase-Estimation/QPE/rz\_lib.py**.

### (a) Computation of the Eigenvalues of States, $2^n$

Given a system of  $n$ -qubits with the pure state  $|i_0, i_1, i_2, \dots, i_n\rangle$ ;  $i_j = \{0, 1\}$ , the eigenvalues of an arbitrary  $R_z^{\otimes n}(\vec{\theta})$  operator can be computed as:

$$2\pi\lambda_{|i_0, i_1, i_2, \dots, i_n\rangle} = -\frac{\sum_k^n (-1)^{i_k}\theta_k}{2} \quad (14)$$

For a set of the eigenvalues,  $\lambda^{[2^n]}$ , is given as:

$$\lambda_{|i_0, i_1, i_2, \dots, i_n\rangle} = -\frac{\sum_k^n (-1)^{i_k}\theta_k}{4\pi} \equiv \lambda_j \quad (15)$$

For an element in the set of eigenvalues,  $\lambda_j$ , is given as:

$$\lambda_i = -\frac{(-1)^i\theta}{4\pi}; \quad (16)$$

The computation of the eigenvalues of the states,  $2^n$ , is implemented with the bulleted list below.

- Computing the States,  $2^n$ , as a Binary String

The first step is the computation of each state,  $2^n$  as a binary string. This is implemented with the **bit\_field** function, which computes the binary string of a given integer.

```

1 def bitfield(n_int: int, size: int):
2     """Transforms an int n_int to the corresponding bitfield
3         of size size
4
4     Parameters
5     -----
6     n_int : int
7         integer from which we want to obtain the bitfield
8     size : int
9         size of the bitfield
10
11    Returns
12    -----
13    full : list of ints
14        bitfield representation of n_int with size size
15
16    """
17    aux = [1 if digit == "1" else 0 for digit in bin(n_int)
18 [2:]]
18    right = np.array(aux)

```

## 4.1 Implementation of the QPE Benchmark Test Case

```

19     left = np.zeros(max(size - right.size, 0))
20     full = np.concatenate((left, right))
21     return full.astype(int)

```

Listing 25: Computing  $2^n$  as a binary string

- **Computing the corresponding eigenvalue,  $\lambda_j$ , of each state,  $|j\rangle$**

The second step, is the computation of the corresponding eigenvalue,  $\lambda_j$ , of each state,  $|j\rangle$ . This is implemented with the **rz\_eigv\_from\_state** function, which takes as an argument, the output from the **bit\_field** function and the  $n$  angles,  $\vec{\theta}$ , and returns the eigenvalue of the respective state:

```

1 def rz_eigv_from_state(state, angles):
2     """
3         For a fixed input state and the angles of the R_z^n
4         operator compute
5             the correspondent eigenvalue.
6
7         Parameters
8         -----
9
10        state : np.array
11            Array with the binnary representation of the input
12            state
13        angles: np.array
14            Array with the angles for the R_z^n operator.
15
16        Returns
17        -----
18
19        lambda_ : float
20            The eigenvalue for the input state of the R_z^n
21            operator with
22            the input angles
23
24        """
25        new_state = np.where(state == 1, -1, 1)
26        # Computing the eigenvalue correspondent to the input
27        # state
28        thetas = - 0.5 * np.dot(new_state, angles)
29        # We want the angle between [0, 2pi]
30        thetas_2pi = np.mod(thetas, 2 * np.pi)
31        # Normalization of the angle between [0,1]
32        lambda_ = thetas_2pi / (2.0 * np.pi)
33        return lambda_

```

Listing 26: The **rz\_eigv\_from\_state** function for computing the respective eigenvalues for each state,  $2^n$ .

## 4.1 Implementation of the QPE Benchmark Test Case

### (b) Obtaining the Histogram plot for the Theoretical Probability Distribution

A histogram plot that corresponds to the complete list of the eigenvalues,  $\lambda^{\otimes[2^n]}$ , must be obtained for all possible states,  $2^n$ . The bulleted list below explains the implementation steps for this.

- **Computing the complete list of the eigenvalues,  $\lambda^{\otimes[2^n]}$ :** The function, `rz_eigv`, takes as an argument the list of  $n$  angles and returns a pandas Dataframe object of all the eigenvalues of the arbitrary  $R_z(\theta)$ , unitary operator.

```

1 def rz_eigv(angles):
2     """
3         Computes the complete list of eigenvalues for a R_z^n
4             operator
5                 for a input list of angles
6                     Provides the histogram between [0,1] with a bin of 2**n
7                         discretization
8                             for the distribution of eigenvalues of a R_z^n operator
9                                 for a given
10                                    list of angles.
11
12    Parameters
13    -----
14
15    angles: np.array
16        Array with the angles for the R_z^n operator.
17
18    Returns
19    -----
20
21    pdf : pandas DataFrame
22        DataFrame with all the eigenvalues of the R_z^n
23        operator for
24            the input list angles. Columns
25                * States : Eigenstates of the Rz^n operator (
26                    least
27                        significative bit is leftmost)
28                * Int_lsb_left : Integer conversion of the state
29                    (leftmost lsb)
30                * Int_lsb_rightt : Integer conversion of the
31                    state
32                        (rightmost lsb)
33                * Eigenvalues : correspondent eigenvalue
34
35    """
36
37    n_qubits = len(angles)
38    # Compute eigenvalues of all possible eigenstates
39    eigv = [rz_eigenv_from_state(bitfield(i, n_qubits),
40                                angles)\n
41            for i in range(2**n_qubits)]

```

#### 4.1 Implementation of the QPE Benchmark Test Case

```

35     pdf = pd.DataFrame(
36         [eigv],
37         index=['Eigenvalues']
38     ).T
39     pdf['Int_lsb_left'] = pdf.index
40     state = pdf['Int_lsb_left'].apply(
41         lambda x: bin(x)[2:].zfill(n_qubits)
42     )
43     pdf['States'] = state.apply(lambda x: ' | ' + x[::-1] + '>'
44     ')
44     pdf['Int_lsb_right'] = state.apply(lambda x: int('0b'+x
45    [::-1], base=0))
45     pdf = pdf[['States', 'Int_lsb_left', 'Int_lsb_right', 'Eigenvalues']]
46
46     return pdf

```

Listing 27: The `rz_eigv` function for computing a complete list of the eigenvalues,  $\lambda^{\otimes[2^n]}$ .

It is important to note that, for the *option of exact choice of angles* (see subsection 4.1.2), depending on the angles,  $\vec{\theta}$ , for the operator,  $R_z^{\otimes n}(\vec{\theta})$ , some eigenvalues can have degeneracy (occurring several times). In this case, the less frequent eigenvalue and its frequency should be stored.

- **Obtaining the corresponding Histogram of the Eigenvalues, given in,  $\lambda^{\otimes[2^n]}$ :**

For the complete list of eigenvalues obtained from the `rz_eigv` function, we need to generate the corresponding Histogram in the range  $[0, 1]$  with  $2^m$ ,  $k$ -bins. In each bin, the histogram contains information about the frequency of the eigenvalues,  $f_{\lambda k}$ . The generation of the histogram is done with the `make_histogram` function. And the frequency,  $f_{\lambda k}$ , corresponds to the discrete Theoretical Probability Distribution of the eigenvalues,  $P_{\lambda, m}^{th}(\frac{k}{2^m})$ , where  $m$  is the discretization parameter, fixed for a number of auxiliary qubits.

```

1 def make_histogram(eigenvalues, discretization):
2     """
3         Given an input list of eigenvalues compute the
4         correspondent
5         histogram using a bins = 2^discretization
6
7     Parameters
8     -----
9
10    eigenvalues : list

53
54     return pdf

```

Listing 28: The **make\_histogram** function for generating the histogram corresponding to the complete list of eigenvalues,  $\lambda^{\otimes[2^n]}$ .

## 2. Implementation of the Reference / Theoretical Probability Distribution of the eigenvalues of R\_z using the QPE\_RZ class

Using the **QPE\_RZ** class (see subsection 4.1.2), the generation of the reference probability can be obtained with the **theoretical\_distribution** method. This method calls the functions, **rz\_eigv** and **make\_histogram** from the **rz\_library** for computing the eigenvalues,  $\lambda^{\otimes[2^n]}$  and generating a histogram for building the theoretical probability distribution,  $P_{\lambda,m}^{th}(\frac{k}{2^m})$ .

#### 4.1 Implementation of the QPE Benchmark Test Case

This function also calls the **computing\_shots** function for computing the number of shots for simulating the Quantum Circuit discussed in step 4.

```

1 def theoretical_distribution(self):
2     """
3         Computes the theoretical distribution of Rz eigenvalues
4     """
5     # Compute the complete eigenvalues
6     self.theoretical_eigv = rz_lib.rz_eigv(self.angles)
7     # Compute the eigenvalue distribution using
8     auxiliar_qbits_number
9     self.theoretical_eigv_dist = rz_lib.make_histogram(
10        self.theoretical_eigv['Eigenvalues'], self.
11        auxiliar_qbits_number)
12     if self.shots is None:
13         # Compute the number of shots for QPE circuit
14         self.shots = rz_lib.computing_shots(self.theoretical_eigv
15    )
16     else:
17         if self.shots != 0:
18             self.shots = rz_lib.computing_shots(self.
theoretical_eigv)
19         else:
20             pass

```

Listing 29: The **theoretical\_distribution** method of the **QPE\_RZ** class for generating the Theoretical Probability Distribution of the  $R_z$  eigenvalues.

Now, we discuss the implementation of the steps for executing the **QPE kernel** on the quantum device.

### 3. Computation of the Number of Shots for Simulating the QPE Circuit on the Quantum Device

The function **computing\_shots** in the **rz\_library** computes the number of shots:

$$n_{shots} = \frac{1000}{0.81 * f_{\lambda_{lf}}}; f_{\lambda_{lf}} \text{ is the frequency of the less frequent eigenvalue.} \quad (17)$$

for executing the **QPE Quantum Circuit** in subsection 4a. This function is implemented such that, the least occurring eigenvalues are measured at least 1000 times; it takes as an argument, the *Pandas DataFrame* containing the theoretical probability distribution and returns the number of shots for the **QPE** algorithm.

```

1 def computing_shots(pdf):
2     """
3         Compute the number of shots. The main idea is that the samples
4         for
5         the lowest degeneracy eigenvalues will be enough. In this case
6         enough is that that we measured an eigenvalue that will have an
7         error from respect to the theoretical one lower than the

```

19      number of shots for QPE algorithm
20
21  """
22  # prob of less frequent eigenvalue
23  lfe = min(pdf.value_counts('Eigenvalues')) / len(pdf)
24  shots = int((1000 / (lfe * 0.81))) + 1
25  return shots

```

Listing 30: The `computing_shots` function, for executing and measuring the QPE circuit on the quantum device n-times

## 4. Generation of the Quantum QPE Probability Distribution of the Eigenvalues of R\_z using the rz\_library

In this section, we discuss the steps and functions for generating a QPE probability distribution,  $P_{\lambda,m}^{QPE}\left(\frac{k}{2^m}\right)$ ;  $k = 1, 2, \dots, 2^m$  of the eigenvalues. The implemented functions for this step are located in the files `rz_lib.py` and `rz_qlm.py` in the `sourceCodeCases/03-Phase-Estimation/QPE` folder of the attached file. The bulleted list below explains the implementation steps for this.

### (a) Building the Quantum Circuit

Here we discuss the implementation of the quantum circuit for obtaining the Quantum probability distribution.

#### i. Building the $R_z^{\otimes n}(\vec{\theta})$ operator:

The `rz_angles` function from the `rz_library`, located in `sourceCodeCases/03-Phase-Estimation/QPE/rz_lib.py` allows for the building of the  $R_z^{\otimes n}(\vec{\theta})$  operator shown in figure 6, with the input  $n$  angles. It creates a QLM abstract gate with the  $R_z^{\otimes n}(\vec{\theta})$  for an input array of angles.

#### 4.1 Implementation of the QPE Benchmark Test Case

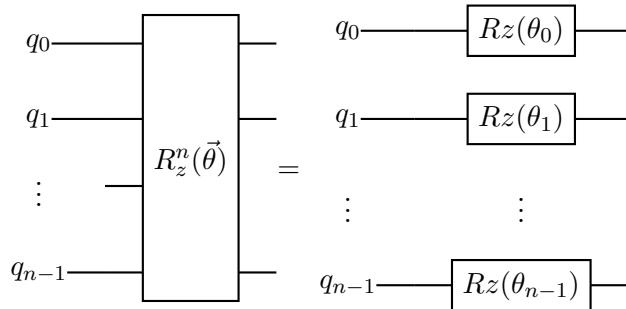

Figure 6: Circuit implementation of the  $R_z^n(\vec{\theta})$  operator

```

1 def rz_angles(thetas):
2     """
3         Creates a QLM abstract Gate with a R_z^n operator of an
4         input array of angles
5
6         Parameters
7
8             -----
9             thetas : array
10                Array with the angles of the R_z^n operator
11
12        Returns
13
14        -----
15        r_z_n : QLM AbstractGate
16            AbstractGate with the implementation of R_z^n of
17            the input angles
18
19        """
20        n_qbits = len(thetas)
21
22        @qlm.build_gate("Rz_{}".format(n_qbits), [], arity=
23        n_qbits)
24        def rz_routine():
25            routine = qlm.QRoutine()
26            q_bits = routine.new_wires(n_qbits)
27            for i in range(n_qbits):
28                routine.apply(qlm.RZ(thetas[i]), q_bits[i])
29            return routine
30        r_z_n = rz_routine()
31        return r_z_n

```

Listing 31: The function, `rz_angles` for building the  $R_z^{\otimes n}(\vec{\theta})$  operator.

#### 4.1 Implementation of the QPE Benchmark Test Case

- ii. **Computing the Initial State,  $\Psi_0$  of the  $R_z^{\otimes n}(\vec{\theta})$  operator:** This is implemented with the Hadamard,  $H$ -operator, which puts the,  $2^n$  state in a linear combination of state, as shown in lines 243 - 246, in the file **rz\_lib.py** and lines 45 - 48, in the file **rz\_qlm.py**.

```

1 # Creating the superposition initial state
2 for i in range(n_qbits):
3     #print(i)
4     initial_state.apply(qlm.H, q_bits[i])
5

```

Listing 32: Initial state of the  $R_z^{\otimes n}(\vec{\theta})$  operator.

- iii. **Building the QPE circuit:** For a particular configuration of the **PE** (that is, exact or random configuration) kernel for the  $R_z^{\otimes n}(\vec{\theta})$  operator, the **CQPE** class which implements the Classical Quantum Phase Estimation using the inverse of the Quantum Fourier Transform, builds the **QPE** circuit shown in figure 7. The **CQPE** is shown in listing 33 and is located in **sourceCodeCases/03-Phase-Estimation/QPE/qpe.py**.

Listing 33: The **CQPE** class for Building and Simulating the QPE Quantum Circuit.

### (b) Obtaining the Histogram Plot for the QPE Probability Distribution

As in the case of the theoretical probability distribution,  $P_{\lambda,m}^{th}(\frac{k}{2^m})$ , a histogram plot that corresponds to the complete list of the eigenvalues,  $\lambda^{[2^n]}$ , must be obtained for all possible states,  $2^n$  for building the QPE probability distribution,  $P_{\lambda,m}^{QPE}(\frac{k}{2^m})$ . The bulleted list below explains the implementation steps for this.

- i. Computing the complete list of the eigenvalues,  $\lambda^{\otimes[2^n]}$ :

- Simulating the Quantum Circuit:

The,  $R_z^{\otimes n}(\vec{\theta})$  operator and its initial state,  $\Psi_0$  in subsection 4a.1, is provided to the **qpe\_rz qlm** function of the **rz\_library** (see listing 34), and is simulated by calling the *run* method of the **CQPE** class, shown in listing 33.

- The complete list of the eigenvalues: This is obtained by the **qpe\_rz qlm** function of the **rz\_library**.

```

1     qft_pe = CQPE(**qft_pe_dict)
2     qft_pe.run()
3     qft_pe_results = qft_pe.result
4     qft_pe_results.sort_values('lambda', inplace=True)
5     results = qft_pe_results[['lambda', 'Probability']]
6     results.reset_index(drop=True, inplace=True)
7     return results, qft_pe
8

```

Listing 34: Code section from the **qpe\_rz qlm** function from the **rz\_library** for computing the complete list of the eigenvalues,  $\lambda^{\otimes[2^n]}$ , for the Quantum Probability Distribution.

- ii. Obtaining the corresponding histogram of the eigenvalues, given in,  $\lambda^{\otimes[2^n]}$ :

For the complete list of eigenvalues obtained from the **qpe\_rz qlm** function, we need to generate the corresponding Histogram as in the case of the Reference/Theoretical Probability Distribution. This histogram is in the range [0, 1] with  $2^m$ ,  $k$ -bins. In each bin, the histogram contains information about the frequency of the eigenvalues,

## 4.1 Implementation of the QPE Benchmark Test Case

$f_{\lambda k}$ . The generation of the histogram is done with the **make\_histogram** function (listing 28) in the **rz\_library**. And the frequency,  $f_{\lambda k}$ , corresponds to the discrete QPE probability distribution of the eigenvalues,  $P_{\lambda, m}^{QPE}(\frac{k}{2^m})$ , where  $m$  is the discretization parameter, fixed for a number of auxiliary qubits.

### 5. Implementation of the Quantum probability distribution of the eigenvalues of R\_z using the QPE\_RZ class

The computation of the QPE Probability Distribution, is implemented with the **quantum\_distribution** method of the **QPE\_RZ** class.

```

1 def quantum_distribution(self):
2     """
3         Computes the quantum distribution of Rz eigenvalues
4     """
5     self.quantum_eigv_dist, qpe_object = rz_lib.qpe_rz_qlm(
6         self.angles,
7         auxiliar_qbits_number=self.auxiliar_qbits_number,
8         shots=self.shots,
9         qpu=self.qpu
10    )
11    self.circuit = qpe_object.circuit
12    self.quantum_time = qpe_object.quantum_times
13

```

Listing 35: The **quantum\_distribution** method of the **QPE\_RZ** class for generating the QPE Probability Distribution of the  $R_z$  eigenvalues.

## 6. Computing the metrics

The Probability Distributions obtained for the theoretical implementation,  $P_{\lambda, m}^{th}(\frac{k}{2^m})$ , and the QPE implementation,  $P_{\lambda, m}^{QPE}(\frac{k}{2^m})$ , is compared with **The Kolmogorov-Smirnov(KS)** and **fidelity** metric, implemented in the **get\_metrics** method of the **QPE\_RZ** class, shown in listing 36.

It is important to note here that, the results of the **KS** and **fidelity** metric is relative to the configuration of the **QPE kernel**. While the **KS** metric is a good metric for both *random* and *exact* configurations of the **QPE kernel**, the **fidelity** metric is best for the *exact* configuration of the **QPE kernel**. The notebook in **sourceCodeCases/03-Phase-Estimation/02\_BTC\_03\_QPE\_for\_rzn\_Procedure.ipynb**, illustrates this relativity.

```

1 def get_metrics(self):
2     """
3         Computing Metrics
4     """
5     # Kolmogorov-Smirnov
6     self.ks = np.abs(
7         self.theoretical_eigv_dist['Probability'].cumsum() \
8             - self.quantum_eigv_dist['Probability'].cumsum()
9     ).max()
10    # Fidelity

```

#### 4.1 Implementation of the QPE Benchmark Test Case

```

11     qv = self.quantum_eigv_dist['Probability']
12     tv = self.theoretical_eigv_dist['Probability']
13     self.fidelity = qv @ tv / (np.linalg.norm(qv) * np.linalg.
norm(tv))

```

Listing 36: `get_metrics` method for computing the metrics for  $P_{\lambda,m}^{th}(\frac{k}{2^m})$  and  $P_{\lambda,m}^{QPE}(\frac{k}{2^m})$ .

## 7. Implementing the complete QPE Benchmark Test Case

The `QPE_RZ` class for implementing the complete **QPE** Benchmark Test Case is given in listing 37 and a demonstration of its usage is given in the notebook located in `sourceCodeCases/03-Phase-Estimation/QPE/qpe_rz.py`.

Listing 37: The **QPE\_RZ** class for executing the complete QPE Benchmark Test Case.

## 4.2 Execution of the Complete QPE Benchmark Procedure

The action of the **my\_benchmark\_execution.py** script is discussed in this section. This script is a modification of the corresponding template script located in **sourceCodeCases/templates** folder of the attached file. The functions, **run\_code**, **compute\_samples** and **summarize\_results** were modified; however, the **KERNEL\_BENCHMARK** class was not modified. The software adaptions for the **PE kernel** are presented in the subsequent sections.

## 4.2 Execution of the Complete QPE Benchmark Procedure

### run\_code

Listing 38 shows the modifications of the `run_code` function for the **Benchmark Test Case** of the **QPE kernel**. The main functionality of the function is executing the **Benchmark Test Case** for a fixed number of qubits (`n_qbits`), auxiliary qubits, (`aux_qbits`), angles, repetitions for each execution of the benchmark, (`repetitions`), specifying a benchmark stage and gathering all the mandatory metrics obtained. Listing 38 shows the `qpe_rz` class and its `exe` method for the execution of the **PE Benchmark Test Case**.

```

1 def run_code(n_qbits, repetitions, **kwargs):
2     """
3         For configuration and execution of the benchmark kernel.
4
5     Parameters
6     -----
7
8     n_qbits : int
9         number of qubits used for domain discretization
10    repetitions : list
11        number of repetitions for the integral
12    kwargs : keyword arguments
13        for configuration of the benchmark kernel
14
15    Returns

68 return list(samples_)

```

Listing 39: `compute_samples` function for codifying the strategy for computing the number of repetitions for the **Benchmark Test Case** of the **QPE kernel**.

### summarize\_results

Listing 40 shows the implementation of the `summarize_results` function for the **Benchmark Test Case** of the **QPE kernel**. The main objective of the function is post-processing the results of the complete **Benchmark Test Case** execution.

This function expects that the results of the complete benchmark execution have been stored in a csv file. The function loads this file into a pandas DataFrame that is post-processed properly.

```

1 def summarize_results(**kwargs):
2     """
3     Create summary with statistics
4     """
5
6     folder = kwargs.get("saving_folder")
7     csv_results = folder + kwargs.get("csv_results")
8
9     #Code for summarize the benchamark results. Depending of the
10    #kernel of the benchmark
11    pdf = pd.read_csv(csv_results, index_col=0, sep=";")
12    pdf["classic_time"] = pdf["elapsed_time"] - pdf["quantum_time"]
13    # The angles are randomly selected. Not interesting for aggregation
14    pdf.drop(columns=['angles'], inplace=True)
15    results = pdf.groupby(["n_qbits", "aux_qbits", "angle_method"]).agg(
16        [
17            ["mean", "std", "count"] + \
18            [('std_mean', lambda x: np.std(x)/np.sqrt(len(x)))]]
19    )
20    results.drop(columns=[
21        ('delta_theta', 'std'),
22        ('delta_theta', 'count'),
23        ('delta_theta', 'std_mean'),
24        ('shots', 'std'),
25        ('shots', 'count'),
26        ('shots', 'std_mean')], )

```

## 4.2 Execution of the Complete QPE Benchmark Procedure

```

25     inplace=True
26 )
27
28 results['qpu'] = [''.join(list(b_['qpu'].unique())) for a_, b_ \
29     in pdf.groupby(['n_qbits', 'aux_qbits', 'angle_method'])]
30 #results = pd.DataFrame()
31 return results

```

Listing 40: **summarize\_results** function for summarizing the results from the **Benchmark Test Case** execution of the **QPE kernel**.

### KERNEL\_BENCHMARK class

This python class defines the complete benchmark workflow and its *exe* method executes it properly by calling the correspondent functions (**run\_code**, **compute\_samples**, **summarize\_results**). Each time the **Benchmark Test Case** is executed, the result is stored in a given CSV file.

The only mandatory modification is properly configuring the input keyword arguments at the end of the **my\_benchmark\_execution.py** script. These parameters will configure the **PE** algorithm, that is, the complete benchmark workflow, and additional options (like the name of the CSV files).

Listing 41 shows an example for configuring an execution of a Benchmark Test Case: in this case, the **PE kernel** for the  $R_z^{\otimes n}(\vec{\theta})$  operator is configured with *random* angles and *exact* angles; the *random* configuration is evaluated based on the **Kolmogorov-Smirnov (KS)** metric, while the *exact* configuration is evaluated based on the *fidelity* metric.

```

1 if __name__ == "__main__":
2
3     import os
4     import shutil
5
6     kernel_configuration = {
7         "angles" : ["random", 'exact'],
8         'auxiliar_qbits_number' : [4, 6, 8, 10],
9         "qpu" : "default", #python, qlmass, default
10        "fidelity_error" : 0.001,
11        "ks_error" : 0.05
12    }
13
14     benchmark_arguments = {
15         #Pre benchmark sttuff
16         "pre_benchmark": True,
17         "pre_samples": [15, 20],
18         "pre_save": False,
19         #Saving stuff
20         "save_append" : True,
21         "saving_folder": "./Results/",
22         "benchmark_times": "kernel_times_benchmark.csv",
23         "csv_results": "kernel_benchmark.csv",
24         "summary_results": "kernel_SummaryResults.csv",
25         #Computing Repetitions stuff
26         "alpha": 0.05,

```

### 4.3 Generation of the QPE Benchmark Report

```

27     "min_meas": 20,
28     "max_meas": None,
29     #List number of qubits tested
30     "list_of_qbits": [4, 6, 8, 10, 12],
31 }
32
33 #Configuration for the benchmark kernel
34 benchmark_arguments.update({"kernel_configuration":
35     kernel_configuration})
36     kernel_bench = KERNEL_BENCHMARK(**benchmark_arguments)
37     kernel_bench.exe()

```

Listing 41: Example of configuration of a complete **Benchmark Test Case** execution. This part of the code should be located at the end of the **my\_benchmark\_execution.py** script.

Possible *kwargs* for the **KERNEL\_BENCHMARK** class, *benchmark\_arguments* dictionary in listing 20 are:

- *pre\_benchmark*: For executing or not executing the *pre-benchmark* step.
- *pre\_samples*: number of repetitions of the benchmark step. The first element is for the integration interval **0** and the second for the interval **1**.
- *pre\_save*: For saving or not the results from the *pre-benchmark* step.
- *saving\_folder*: Path for storing all the files generated by the execution of the **KERNEL\_BENCHMARK** class.
- *benchmark\_times*: name for the *csv* file where the initial and the final times for the complete benchmark execution will be stored.
- *csv\_results*: name for the *csv* file where the obtained metrics for the different repetitions of the benchmark step will be stored.
- *summary\_results*: name for the *csv* file where the post-processed results (using the **summarize\_results** function) will be stored.
- *list\_of\_qbits*: list with the different number of qubits for executing the complete **Benchmark Test Case**.

Other parameters like: *alpha*, *min\_meas* or *max\_meas* that are used for the **compute\_samples** function can be provided too, but for a complete **Benchmark Test Case** execution must be fixed to *0.05*, *20* and *None* respectively.

As shown in listing 41 the configuration of the implementation of **QPE** algorithm is passed in the benchmark arguments arguments under the key *kernel\_configuration*.

For executing the **QPE Benchmark Test Case**, the following command should be used:

```
python my_benchmark_execution.py
```

## 4.3 Generation of the QPE Benchmark Report

The results of a complete **QPE Benchmark Test Case** must be reported in a separate JSON file- **Benchmark.V2.Schema\_modified.json** provided in the sourceCodeCases/templates folder. For automating this process the following files should be modified:

## 4.3 Generation of the QPE Benchmark Report

- `my_environment_info.py`
- `my_benchmark_info.py`
- `my_benchmark_summary.py`
- `benchmark.py`

### 4.3.1 `my_environment_info.py`

This script has the functions for gathering information about the hardware where the **Benchmark Test Case** is executed.

Listing 42 shows an example of the `my_environment_info.py` script. Here the compiled information corresponds to a classic computer because the case was simulated instead of executed in a quantum computer.

```

1
2     import platform
3     import psutil

Listing 42: Example of configuration of the **my\_environment\_info.py** script

In general, it is expected that for each computer used (quantum or classic), the benchmark developer should change this script to properly get the hardware info.

## 4.3 Generation of the QPE Benchmark Report

### 4.3.2 my\_benchmark\_info.py

This script gathers the information under the field *Benchmarks* of the benchmark report. Information about the software, the compilers and the results obtained from an execution of the **Benchmark Test Case** is stored in this field.

Listing 43 shows an example of the configuration of the **my\_benchmark\_info.py** script for gathering the aforementioned information.

```

Listing 43: Example of configuration of the `my_benchmark_info.py` script

The `my_benchmark_info` function gathers all the mandatory information needed by the `Benchmarks` main field of the report (by calling the different functions listed in listing 43). In order to properly fill this field, some mandatory information must be provided as the typical `python kwargs`:

- `times_filename`: this is the complete path to the file where the starting and ending time of the benchmark was stored. This file must be a `csv` one and it is generated when the **KERNEL\_BENCHMARK** class is executed. This information is used by the `my_starttime` and `my_endtime` functions.
- `benchmark_file`: complete path where the file with the summary results of the benchmark are stored. This information is used by the `summarize_results` function from `my_benchmark_summary.py` script (see section 4.3.3).

#### 4.3.3 my\_benchmark\_summary.py

In this script, the `summarize_results` function is implemented. This function formats the results of a complete execution of a **Benchmark Test Case** of the **QPE kernel** with the provided benchmark report format. It can be used for generating the information under the sub-field `Results` of the main field `Benchmarks` in the report.

Listing 44 shows an example of implementation of `summarize_results` function for the **QPE** benchmark procedure.

```

1
2     def summarize_results(**kwargs):
3         """
4             Mandatory code for properly present the benchmark results
5             following
6                 the jsonschema
7             """

```

69             return results

```

Listing 44: Example of configuration of the *summarize\_results* function for **QPE** benchmark

As usual, the *kwargs* strategy is used for passing the arguments that the function can use. In this case, the only mandatory argument is *benchmark\_file* with the path to the file where the summary results of the **Benchmark Test Case** execution were stored.

#### 4.3.4 benchmark.py

The *benchmark.py* script can be used directly for gathering all the **Benchmark Test Case** execution information and results, for creating the final mandatory benchmark report.

It is not necessary to change anything about the class implementation. It is enough to update the information of the *kwargs* arguments for providing the mandatory files for gathering all the information.

In this case, the following information should be provided as arguments for the *exe* method of the **BENCHMARK** class:

- *times\_filename*: complete path where the file with the times of the **Benchmark Test Case** execution was stored.
- *benchmark\_file*: complete path where the file with the summary results of the **Benchmark Test Case** execution was stored.
